## Mitigation costs

# Conventional wisdom

- ITC reduces mitigation costs only in partial equilibrium models.
- Technological change is not a free lunch, it has its own opportunity costs.

## SPECIAL REPORT

# The costs of global warming

Efforts to forecast how Earth's future climate will affect us must consider the economic growth of both rich and poor nations. But there are doubts over the theories being used, as **Quirin Schiermeier** explains.

**D**iscussions of climate change tend to involve uncertainties, and most climate researchers have come to accept the inherent unknowns of their business. After all, the climate models they use to project the course of global warming are generally seen as the best that science can offer. But there is a growing feeling that the economic assumptions on which their work is based are outdated and unreliable. And this could have serious implications for assessments of climate change.

The Intergovernmental Panel on Climate Change (IPCC), which coordinates efforts to predict the effects of global warming, is currently finalizing its fourth assessment report. It has asked 15 climate groups to run their models using output from a range of different 'scenarios', representing various assumptions about energy use, economic development

reflect how lifestyle and energy demand in both rich and poor countries are likely to change.

Climate researchers are familiar with the problem. "Some emissions scenarios are perhaps already demonstrably wrong," says Erich Roeckner, a climate modeller at the Max Planck Institute for Meteorology in Hamburg, Germany, who has modelled three of them for the IPCC (see "Early results"). "It is possible that all of them are wrong." But most feel that economics is a field they are not qualified to assess.

## Ridiculous assumption?

One key criticism is the assumption that the economies of poor countries will quickly catch up with those of rich nations. "It is ridiculous to assume, as the IPCC does, that rich and poor countries will economically converge as rapidly as the European Union has done over the past

Translating temperature changes into impacts on society is beset with unknowns.

Panel beaters: could low-carbon energy be surprisingly affordable?

**T**ransforming the world's energy industry to stop the flood of greenhouse gases into the atmosphere might actually be quite cheap.

Figures of tens of trillions of dollars are often cited, and used to question whether measures such as the Kyoto Protocol, which attempts to limit carbon emissions, are too expensive. But according to a suite of economic models released late last month, the costs of stabilizing carbon dioxide levels could be tiny — equivalent to setting back the growth of global GDP (gross domestic product) by less than 1% over 100 years; global GDP generally grows 2–3% each year. In some cases, the right policies for limiting carbon emissions could even create a surprising win-win situation, leading

London. “But only if we do the right things.”

The models simulate a complex issue in economics: how government climate policies such as research investment or greenhouse-gas regulation can bring about technological development. It is obvious that technologies evolve, but the processes involved have been factored into economic models only since the late 1990s, in part because it is difficult to untangle how advances occur. The Innovation Modelling Comparison Project, published in a special issue of *The Energy Journal*, is a two-year

**“Reducing greenhouse gases will be relatively cheap — but only if we do the right things.”**

effort involving eleven different models that represent the latest thinking on the problem.

The results are striking. Nine of the models predict that stabilizing carbon dioxide levels at 450 parts per million, widely seen as the most

# Why are hybrid models important for modelling ETC and ITC?

- ITC is channelled at different levels of the economic system
- Important aspects are:
  - Sector and region specific channels
  - Expectations about future investments (time-consistency)
  - Backstop technologies, end-of-pipe and ETC in the fossil fuel sector

# What are hybrid models?

- Hybrid models combine features or modules from different conceptual frameworks in a consistent way
- The different features or modules can be coupled either online or offline

# MIND – A Case for Hybrid Modelling

- Technological Change in the fossil fuel sector is crucial in determining the opportunity costs of climate protection.
- For a realistic estimations of costs and strategies, TC in the following sectors is crucial:
  - Backstop technologies
  - End-of-pipe technologies
  - Extraction and exploration sector
