Life adaptes to climate conditions

- **Boreal coniferous forests** (boreal = northern) is the vegetation zone in which trees can still grow despite cold temperatures. The boreal coniferous forest belt stretches practically across the entire northern hemisphere, around the 60th parallel.
- Spruces, pines, firs and larches are generally the dominant coniferous species in boreal climates. **Mostly conifers.**
- Low precipitation, permafrost, mean temperatures around +5 to -5 C, with significant upward and downward deviations (-30 C in the winter months; up to +20 C in the summer months).

Life adaptes to climate conditions

- Characteristics of **tropical rainforests**: 1. located near the equator, 2. high temperatures, 3. daily precipitation, 4. evergreen vegetation, 5. high species diversity.
- In the tropical rainforest there are **no seasons**. A diurnal climate prevails (opposite: seasonal climate).
- **Mostly broadleaf trees**.

Life adaptes to climate conditions

Bergmannsche Regel Bären

Volumen increases with power 3 (Sphere = $\frac{4}{3} \pi r^3$)
Surface increases with power 2 (Sphere = πr^2)

Bergmann's rule states that animals of the same

Life adaptes to climate conditions

Beispiele

Allen's rule states that mammals in colder regions, for example, have smaller limbs, ears etc. than their closely related species in warmer regions.

Percent of global greenhouse gas emissions.

Changes in global surface temperature relative to 1850–1900

(a) Change in global surface temperature (decadal average) as **reconstructed** (1–2000) and **observed** (1850–2020)

(b) Change in global surface temperature (annual average) as **observed** and simulated using **human & natural** and **only natural** factors (both 1850–2020)

From emissions to temperatures

Business-as-usual in red

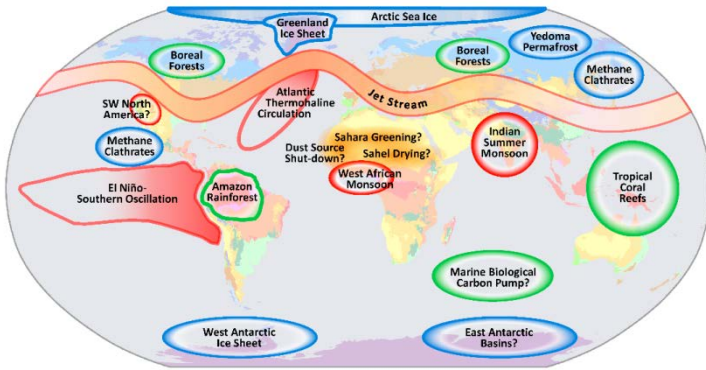

Budget: 400 Gt CO₂
Current annual emission: 40 Gt CO₂

Climate tipping points

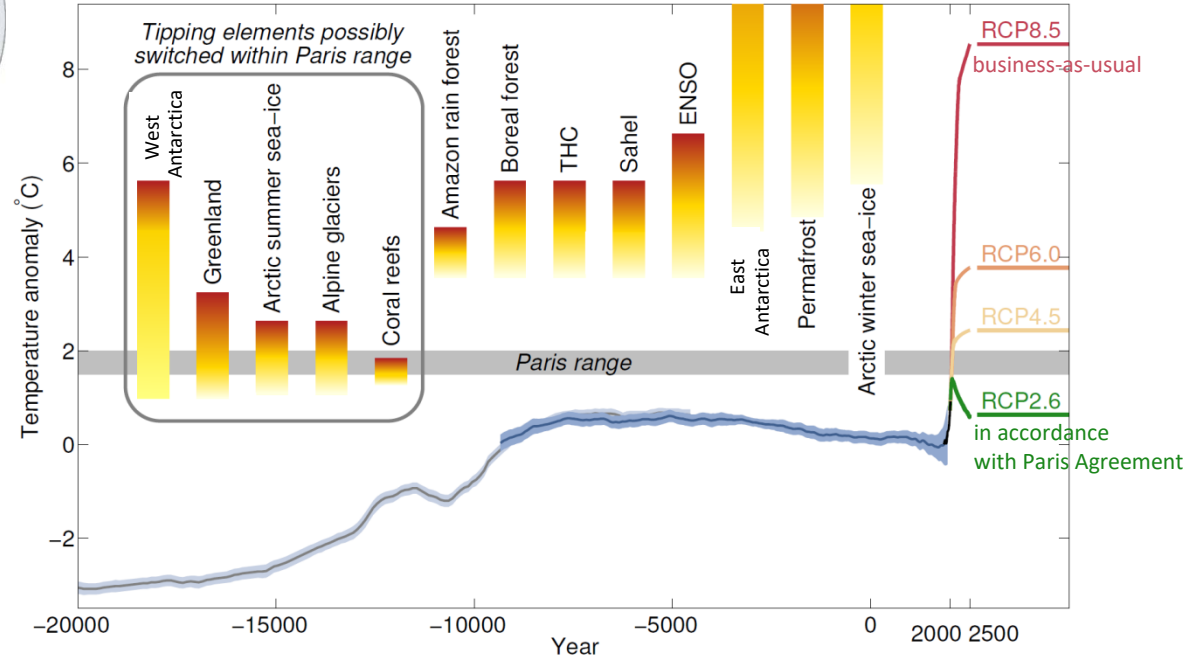

Risks at the horizon

■ Cryosphere Entities
■ Circulation Patterns
■ Biosphere Components

- Humans are a geological force
- Crucial parts of the climate system are at risk of tipping even within the Paris range of 1.5 – 2 °C

UN sustainable development goals

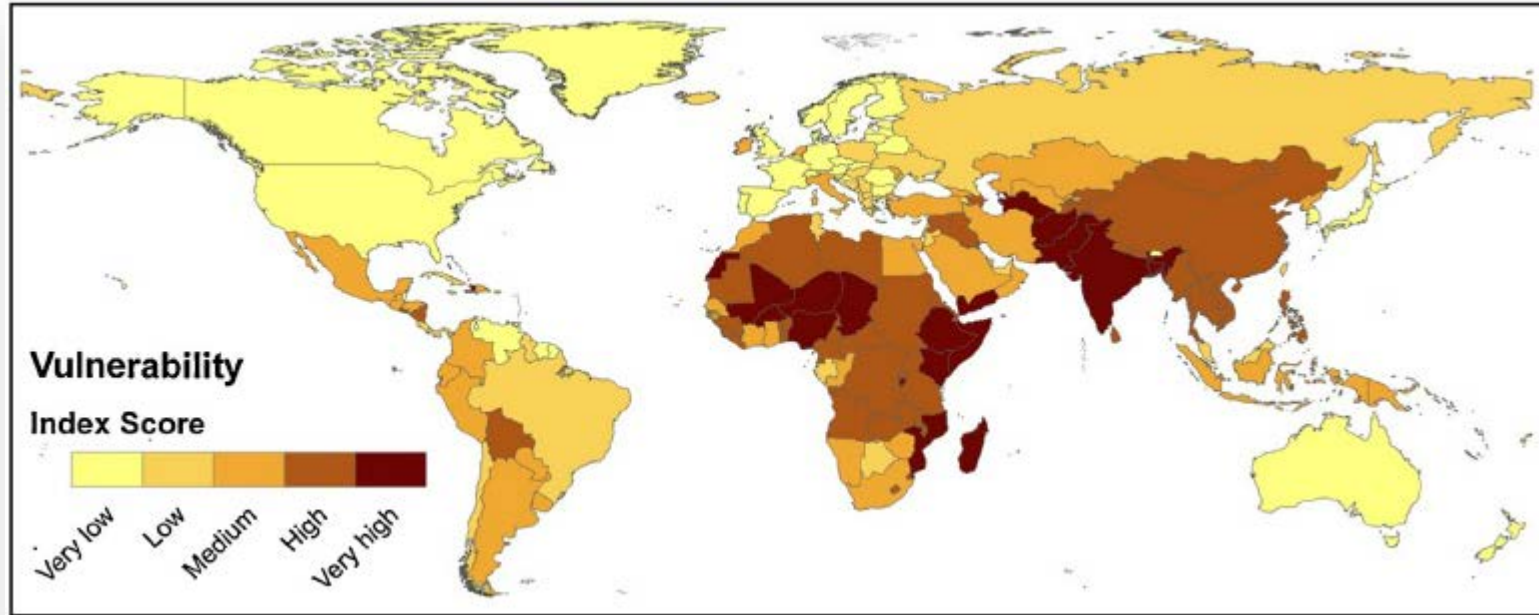

People at risk because of climate change

Intergovernmental Panel on Climate Change (IPCC):

- at least 3.3 billion people's daily lives are “highly vulnerable” to climate change,
- and people are 15 times more likely to die from extreme weather than in years past, the report said.

Climate change vulnerability: Hunger

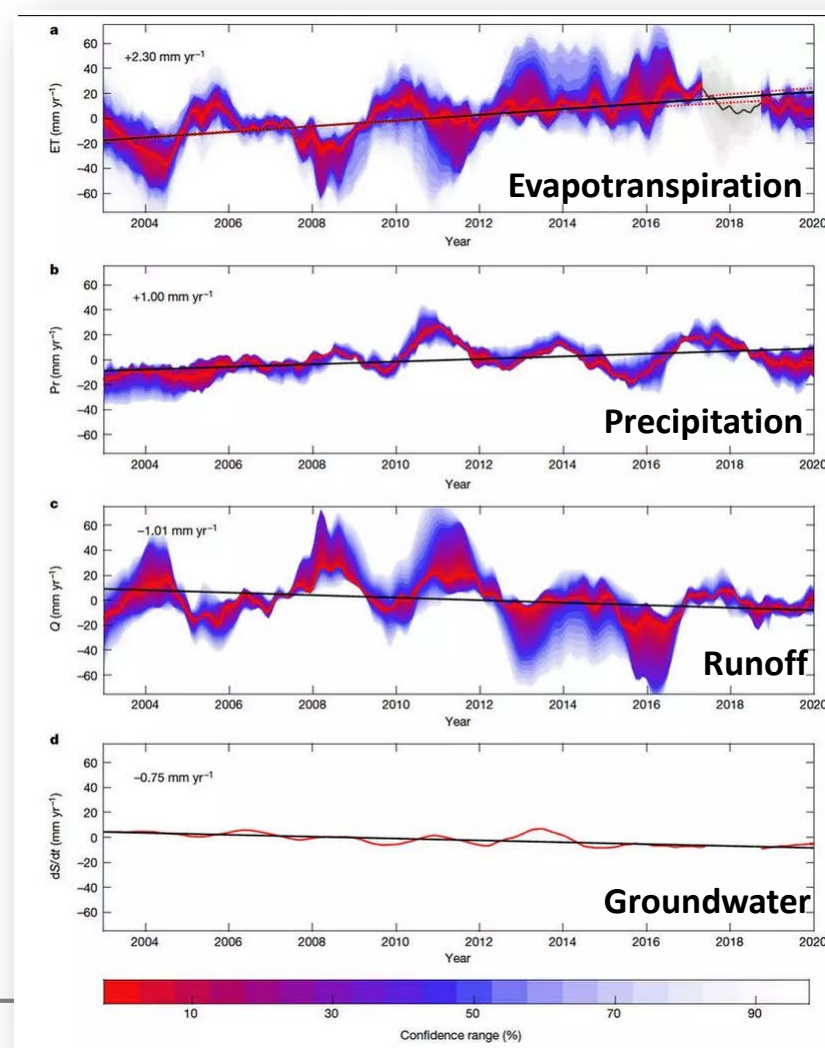

Outline of the three lessons

- Introduction
- Climate – drivers and processes
- Climate and live
- **Observed impacts of climate change**

Global water trends

Gravity Recovery and Climate Experiment (GRACE)

Is this climate change?

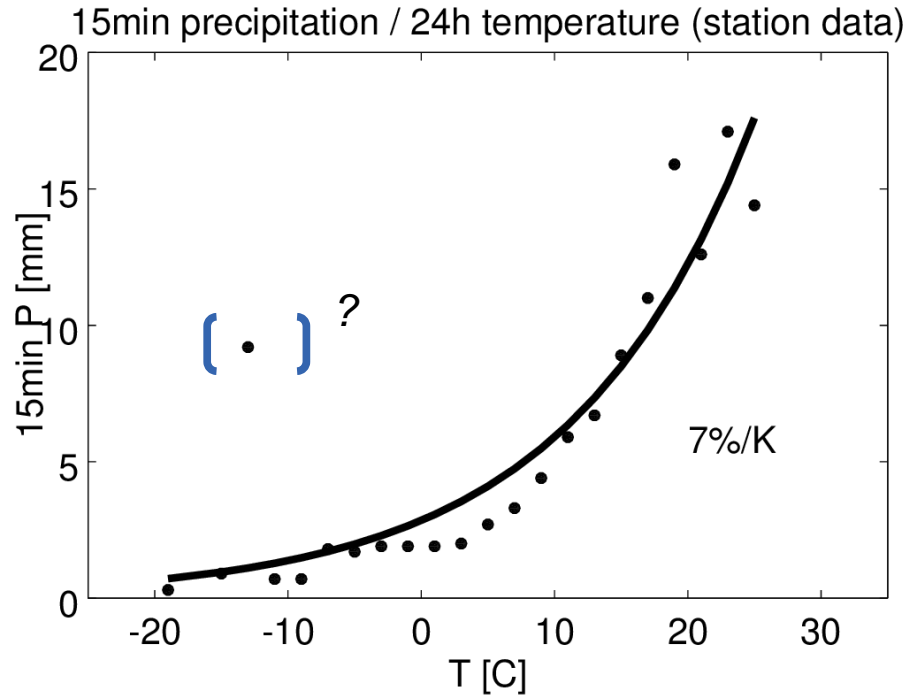

Number of events worldwide (Munich Re NatCat)

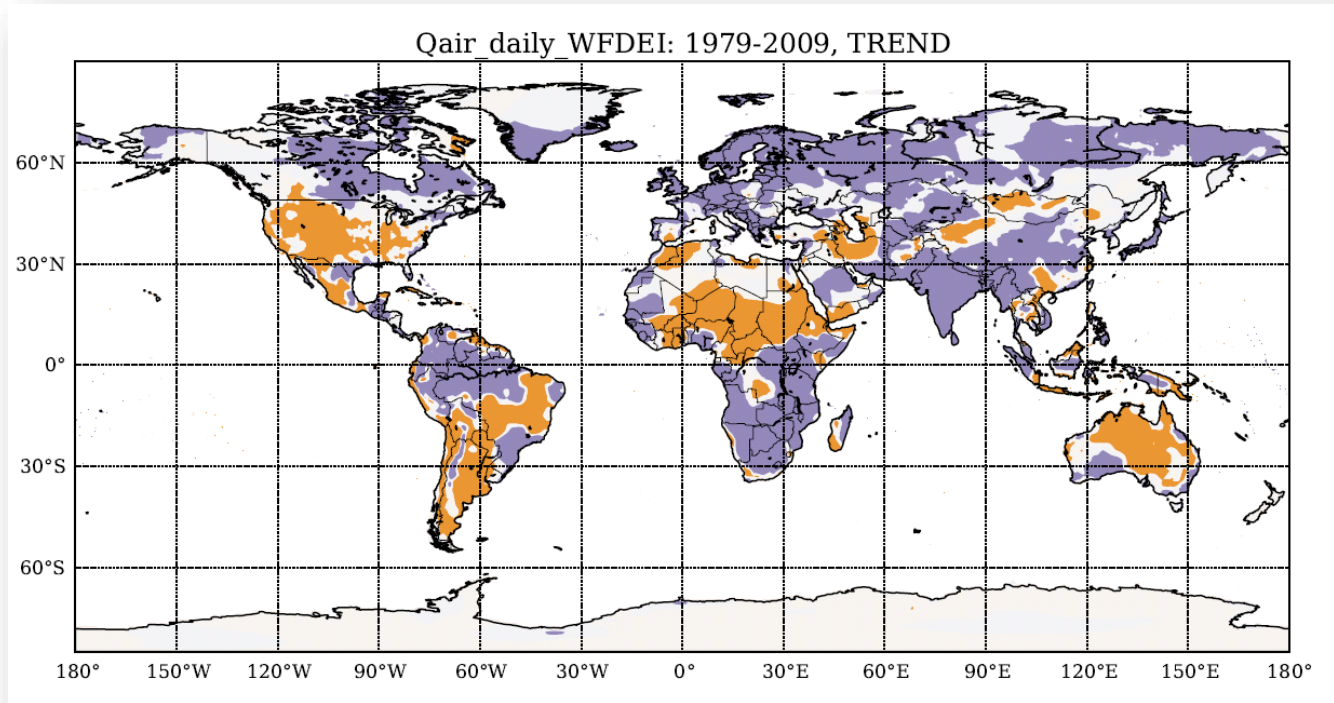

Increase of intense precipitation with temperature

(15min precipitation, 99.9% Quantile, Brixenbachtal, Längental, Ruggbachtal)

Trend in absolute air humidity

Red: decrease, blue: increase
< -0.2g, 0.0%, >0.2g pro 30y

Trend in relative air humidity

Red: decrease, blue: increase
< -0.2g, 0.0%, >0.2g pro 30y

Trends in relative and absolute humidity in Europe

What is the climate change contribution to current extreme events?

- Merz et al. 2012, following IPCC 2007:
- **Detection** in hydrology and related disciplines refers to the demonstration that an observed change is significantly different (in a statistical sense) from changes that can be explained by natural variability.
- **Attribution** is the subsequent attribution of causes to the change.

Four examples

1. **Detection and attribution of heavy precipitation events**
2. **Floods: Land use change or climate change?**
3. **How strong is the influence of climate change on flood risk in Central Europe?**
4. **What if ...**

Example 1: Daily precipitation records

Problem: Extremes are rare events, but for robust statistics you need as much data as possible.

- **Method:**

$$\text{Number of records } N = \sum_{n=1}^n 1/n$$

$$\text{Anomaly of the records } R_{\text{anom}} = \frac{R_{\text{obs}} - R_{1/n}}{R_{1/n}} \times 100(\%)$$

with R_{obs} the number of observed records.

Trick: many time series are lumped in one data basis.

Result: more precipitation records worldwide

- ▶ Saturation vapour pressure regulates daily extreme precipitation.
- ▶ Saturation vapour pressure increases at a rate of 7% per degree of warming (Clausius-Clapeyron).
- ▶ Red area takes temperature rise into account.
- ▶ Also for regions: In Central Europe +31

Example 2: Land use change or climate change?

Germany study

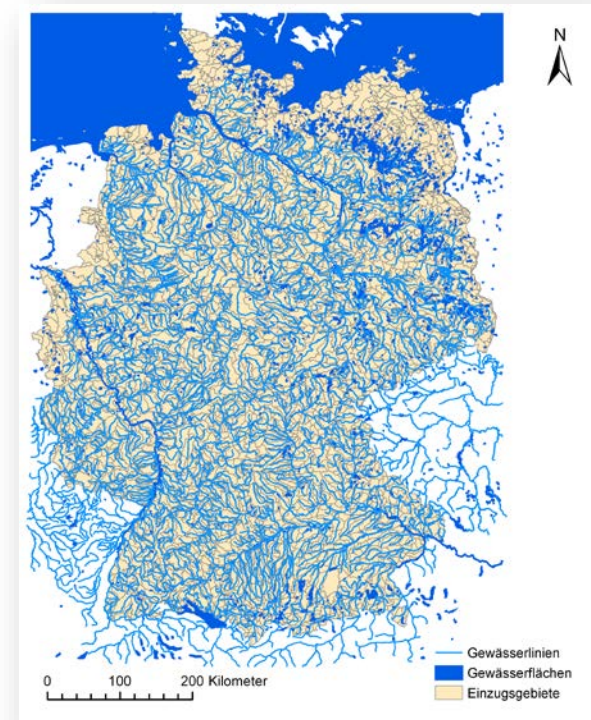

More than 5000 river sections are considered for the five largest rivers in Germany (Rhine, Elbe, Danube, Weser and Ems).

Land use change or climate change?

Trend in annual max. floods 1951-2003

Climate change impacts on flood damages

Example 3: How strong is the influence of climate change on the risk of flooding in Central Europe already now?

- In example 1, a lot of data was saved for statistical analysis by pooling many time series.
- Much of the data for robust analysis can also be generated by computer models.
- Example: <https://www.worldweatherattribution.org> (weather only, not hydrology)
- Example 3: Attribution of changes in flood risk in the Danube River

How extreme are extremes?

DWD: "Deluge at the Mediterranean Sea":

- "... Once connected, this low off Norway was able to pump more and more humidity from hurricane "SAM" across the Atlantic, a so-called atmospheric flow. With a newly formed trough on the Atlantic, this flow moved visibly southwards, so that the moisture could reach the Mediterranean. ..."
- E.g. in Villefort: **459 l/m² within 24 hours**, of which 251 l/m² within 6 hours.
- The record is probably held by the station in Rossiglione with **a breathtaking 848 l/m² in 24 hours - a value beyond any other usual scale**. 700 l/m² of this fell within 12 hours.
- Other stations on the eastern edge of the Massif Central recorded precipitation totals of well over 100 l/m² in 24 hours.

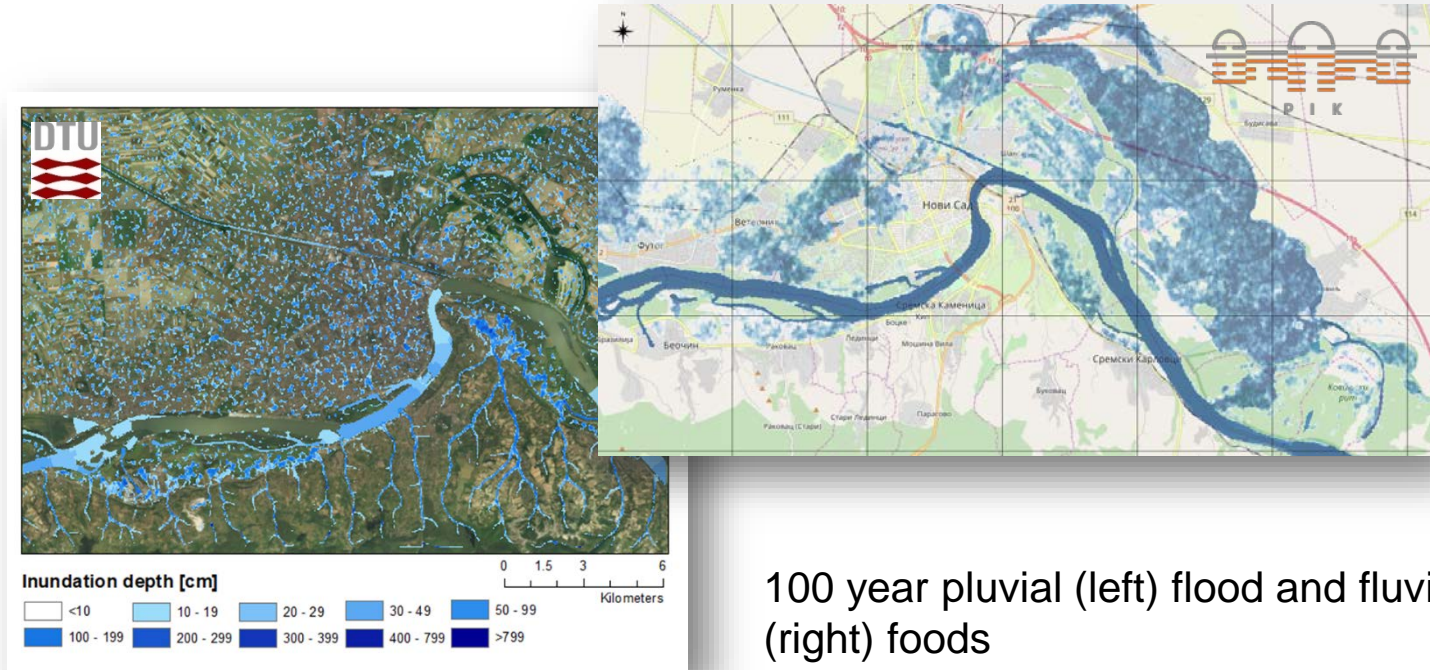

Atmosphärisches Feuchteflussband im Modell ICON von Hurrikan „SAM“ Richtung Mittelmeerraum und Zentraleuropa am 3./4.10.2021

Estimation of runoff parametrization following forest fires

By Konstantinos X. Soulis, DOI: 10.1080/02626667.2018.1501482

Figure 3. Produced total direct runoff depth vs total rainfall depth for the 29 pre-fire and 60 post-fire storm events used in this study. The post-fire events are divided into three chronological sub-groups.

Figure 4. Calculated CN values using Equation (3) for the standard case of $\lambda = 0.2$ plotted against the total rainfall depth for the pre-fire and post-fire periods. The post-fire events are divided into three chronological sub-groups.

SWIM: Water cycle before and after fire

SWIM: Water cycle before and after fire

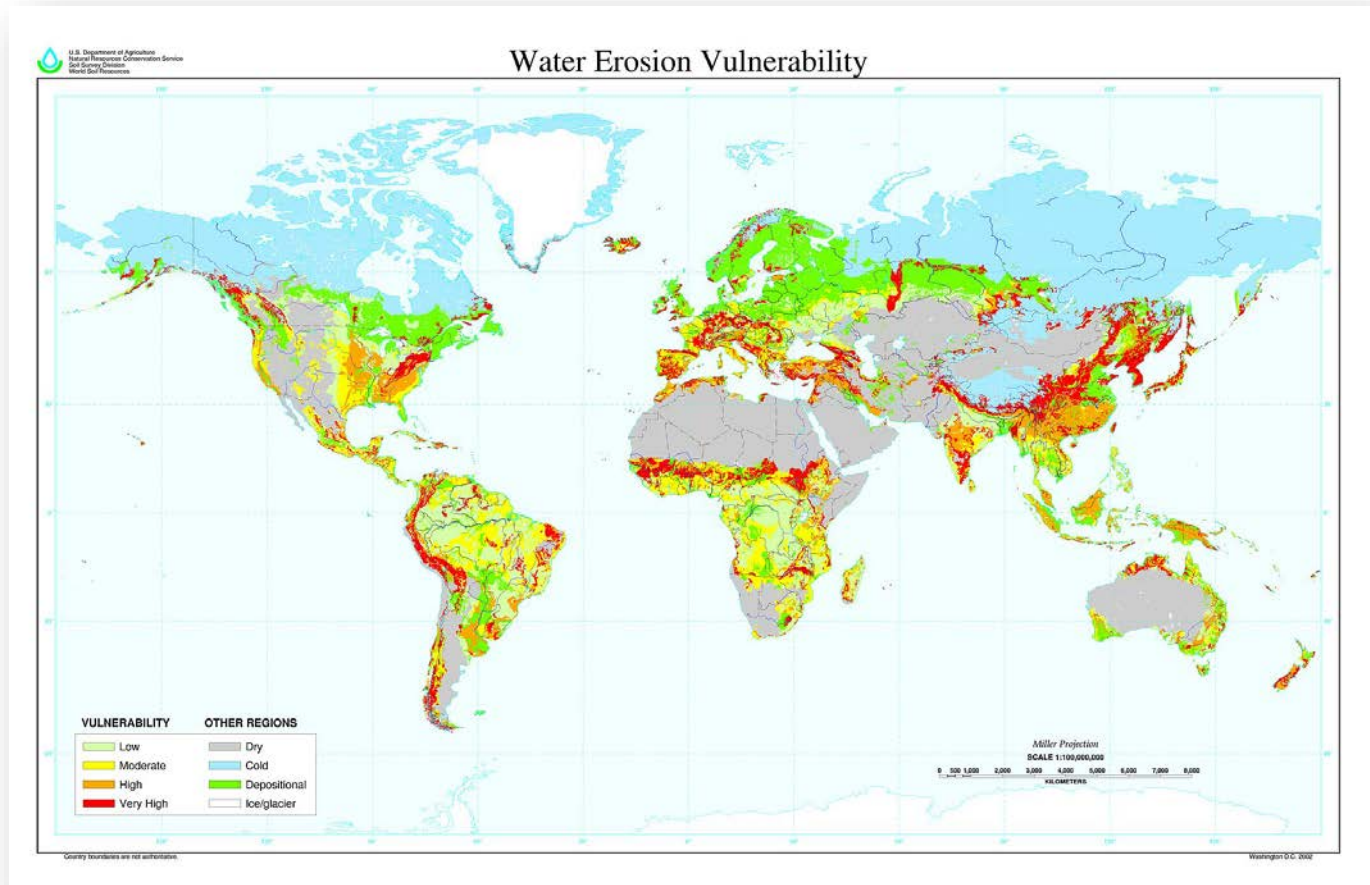

Natural forest:
Surface runoff 112 mm

Burned forest:
Surface runoff: 376 mm

Possibly much more surface runoff in the burned forest areas, so heavy erosion is likely to occur.
